## Abstract

A pure excedance in a permutation  $\pi = \pi_1\pi_2\dots\pi_n$  is a position  $i < \pi_i$ ,  $1 \leq i \leq n - 1$ , so that there is no  $j < i$  such that  $i \leq \pi_j < \pi_i$ . We present a one-to-one correspondence on the symmetric group that transports pure excedances to descents of special kind. As a byproduct, we prove that the popularity of pure excedances equals those of pure descents on permutations, while their distributions are different.

**Keywords:** Permutation, statistic, distribution, popularity, descent, excedance, cycle.

## 1 Introduction and notations

The distribution of the number of descents has been widely studied on several classes of combinatorial objects such as permutations [14], cycles [7, 8], and words [3, 10]. Many interpretations of this statistic appear in several fields as Coxeter groups [4, 11] or lattice theory [5, 12]. One of the most famous result involves the *Foata fundamental transformation* [9] to establish a one-to-one correspondence between descents and excedances on permutations. This bijection provides a more straightforward proof than those of MacMahon [14] for the equidistribution of these two Eulerian statistics.

In this paper, we present a bijection *à la Foata* on the symmetric group that exchanges pure excedances with special kind of descents defined as a mesh pattern  $p_2$  [6] (see below for the definitions of these patterns). Then,

we deduce that the popularities but not the distributions of pure descents [2] and pure excedances are the same. They are given by the generalized Stirling number  $n! \cdot (H_n - 1)$  (see A001705 in [15]) where  $H_n = \sum_{k=1}^n \frac{1}{k}$  is the  $n$ -th harmonic number. Finally, we conjecture the existence of a bijection on the symmetric group that exchanges pure excedances and  $p_2$  while preserving the number of cycles.

Let  $S_n$  be the set of permutations of length  $n$ , *i.e.*, all bijections from  $[n] = \{1, 2, \dots, n\}$  into itself. The one-line representation of a permutation  $\pi \in S_n$  is  $\pi = \pi_1\pi_2 \dots \pi_n$  where  $\pi_i = \pi(i)$ ,  $1 \leq i \leq n$ . For  $\sigma \in S_n$ , the *product*  $\sigma \cdot \pi$  is the permutation  $\sigma(\pi_1)\sigma(\pi_2) \dots \sigma(\pi_n)$ . A  $\ell$ -*cycle*  $\pi = \langle i_1, i_2, \dots, i_\ell \rangle$  is a  $n$ -length permutation satisfying  $\pi(i_1) = i_2, \pi(i_2) = i_3, \dots, \pi(i_{\ell-1}) = i_\ell, \pi(i_\ell) = i_1$  and  $\pi(j) = j$  for  $j \in [n] \setminus \{i_1, i_2, \dots, i_\ell\}$ . For  $1 \leq k \leq n$ , we denote by  $C_{n,k}$  the set of all  $n$ -length permutations admitting a decomposition in a product of  $k$  disjoint cycles. The set  $C_{n,k}$  is counted by the signless Stirling numbers of the first kind  $c(n, k)$  defined by

$$c(n, k) = (n - 1) c(n - 1, k) + c(n - 1, k - 1)$$

where  $c(n, k) = 0$  if  $n \leq 0$  or  $k \leq 0$ , except  $c(0, 0) = 1$  (see [16, 17]). These numbers also enumerate  $n$ -length permutations  $\pi$  having  $k$  *left-to-right maxima*, *i.e.*, values  $i \in [n]$  such that  $\pi_j < \pi_i$  for  $j < i$  (see [16]), and permutations  $\pi \in S_n$  with  $k - 1$  *pure descents*, *i.e.*, descents  $\pi_i > \pi_{i+1}$  where there is no  $j < i$  such that  $\pi_j \in [\pi_{i+1}, \pi_i]$  (see [2]). Note that a pure descent can be viewed as an occurrence of the mesh pattern  $(21, L_1)$  where  $L_1 = \{1\} \times [0, 2] \cup \{(0, 1)\}$ . Indeed, for a  $k$ -length permutation  $\sigma$  and a subset  $R \subseteq [0, k] \times [0, k]$ , an occurrence of the mesh pattern  $(\sigma, R)$  in a permutation  $\pi$  is an occurrence of  $\sigma$  in  $\pi$  with the additional restriction that no element of  $\pi$  lies inside the shaded regions defined by  $R$ , where  $(i, j) \in R$  means the square having bottom left corner  $(i, j)$  in the graphical representation  $\{(i, \sigma_i), i \in [k]\}$  of  $\sigma$ . For instance, an occurrence of the mesh pattern  $p_1$  in Figure 1 corresponds to an occurrence of a pure descent. See [6] for a more detailed definition of mesh patterns.

Regarding this interpretation of pure descents in terms of mesh patterns, we define other kinds of descents by the mesh patterns  $p_i = (21, L_i)$ ,  $p'_i = (21, R_i)$  with  $L_i = \{1\} \times [0, 2] \cup \{(0, i)\}$  and  $R_i = \{1\} \times [0, 2] \cup \{(2, i)\}$  for  $0 \leq i \leq 2$ . Modulo the fundamental symmetries on permutations (reverse and complement), it is straightforward to see that  $p_0, p_1$ , and  $p_2$  are respectively in the same distribution class as  $p'_2, p'_1$  and  $p'_0$ . Then, we deal with only mesh patterns  $p_i, i \in [0, 2]$ . We refer to Figure 1 for a graphical illustration. On the other hand, we define a *pure excedance* as an occurrence of an excedance,

*i.e.*  $\pi_i > i$ , with the additional restriction that there is no point  $(j, \pi_j)$  such that  $1 \leq j \leq i - 1$  with  $i \leq \pi_j < \pi_i$ . Although such a pattern (called *pe<sub>x</sub>*) is not a mesh pattern, we can represent it graphically as shown in Figure 1.

Figure 1: Illustration of the mesh patterns  $p_0$ ,  $p_1$ ,  $p_2$  and *pe<sub>x</sub>*;  $p_1$  and *pe<sub>x</sub>* correspond respectively to a pure descent and a pure excedance.

A *statistic* is an integer-valued function from a set  $\mathcal{A}$  of  $n$ -length permutations (we use the boldface to denote statistics). For a pattern  $p$ , we define the pattern statistic  $\mathbf{p} : \mathcal{A} \rightarrow \mathbb{N}$  where the image  $\mathbf{p} \pi$  of  $\pi \in \mathcal{A}$  by  $\mathbf{p}$  is the number of occurrences of  $p$  in  $\pi$ . The *popularity* of  $p$  in  $\mathcal{A}$  is the total number of occurrences of  $p$  over all objects of  $\mathcal{A}$ , that is  $\sum_{a \in \mathcal{A}} \mathbf{p} a$  (see [5] for instance). Below, we present statistics that we use throughout the paper:

- exc**  $\pi$  = number of excedances in  $\pi$ ,
- pex**  $\pi$  = number of pure excedances in  $\pi$ ,
- des**  $\pi$  = number of descents in  $\pi$ ,
- des<sub>*i*</sub>**  $\pi$  = number of patterns  $p_i$  in  $\pi$ ,  $0 \leq i \leq 2$ ,
- fix**  $\pi$  = number of fixed points in  $\pi$ ,
- cyc**  $\pi$  = number of cycles in the decomposition of  $\pi$ ,
- pcyc**  $\pi$  = number of pure cycles (*i.e.* cycles of length at least two) in  $\pi$ ,  
= **cyc**  $\pi$  - **fix**  $\pi$

We organize the paper as follows. In Section 2, we focus on patterns  $p_i$ ,  $0 \leq i \leq 2$ . We prove that the statistics **des<sub>0</sub>** and **des<sub>1</sub>** are equidistributed by giving algebraic and bijective proofs. Next, we provide the bivariate exponential generating function for the distribution of  $p_2$ , and we deduce that  $p_2$  has the same popularity as  $p_0$  and  $p_1$ , without having the same distribution. In Section 3, we present a bijection on  $S_n$  that transports pure excedances into patterns  $p_2$ . Notice that the Foata's first transformation is not a candidate for such a bijection. As a consequence, pure descents and pure excedances are equipopular on  $S_n$ , but they do not have the same distribution. Combining all these results, we deduce that patterns  $p_i$ ,  $0 \leq i \leq 2$ , and *pe<sub>x</sub>* are equipopular on the symmetric group  $S_n$ . Finally we present two

conjectures about the equidistribution of  $(\mathbf{cyc}, \mathbf{des}_2)$  and  $(\mathbf{cyc}, \mathbf{pex})$ , and that of  $(\mathbf{des}, \mathbf{des}_2)$  and  $(\mathbf{exc}, \mathbf{pex})$ .

## 2 The statistics $\mathbf{des}_i$ , $0 \leq i \leq 2$

For  $0 \leq i \leq 2$ , let  $A_{n,k}^i$  be the set of  $n$ -length permutations having  $k$  occurrences of  $p_i$ , and denote by  $a_{n,k}^i$  its cardinality. Let  $A^i(x, y)$  be the bivariate exponential generating function  $\sum_{n=0}^{\infty} \sum_{k=0}^{n-1} a_{n,k}^i \frac{x^n}{n!} y^k$ . In [2, 13], it is proved that  $a_{n,k}^1$  equals the signless Stirling numbers of the first kind  $c(n, k+1)$  (see A132393 in [15]). Indeed, a permutation  $\sigma \in A_{n,k}^1$  can be uniquely obtained from an  $(n-1)$ -length permutation  $\pi$  by one of the two following constructions:

- (i) if  $\pi \in A_{n-1,k-1}^1$ , then we increase by one all values of  $\pi$  greater than or equal to  $\pi_{n-1}$ , and we add  $\pi_{n-1}$  at the end;
- (ii) if  $\pi \in A_{n-1,k}^1$ , then we increase by one all values of  $\pi$  greater than or equal to a given value  $x \leq n$ ,  $x \neq \pi_{n-1}$  and we add  $x$  at the end.

Then, we deduce the recurrence relation  $a_{n,k}^1 = a_{n-1,k-1}^1 + (n-1)a_{n-1,k}^1$  with  $a_{n,0}^1 = (n-1)!$  for  $n \geq 1$ ,  $a_{0,0}^1 = 1$  and the bivariate exponential generating function is

$$A^1(x, y) = \frac{1}{y(1-x)^y} - \frac{1}{y} + 1$$

which proves that  $a_{n,k}^1 = c(n, k+1)$ .

Below, we prove that  $a_{n,k}^1$  also counts  $n$ -length permutations having  $k$  occurrences of the pattern  $p_0$ .

**Theorem 1.** *The number  $a_{n,k}^0$  of  $n$ -length permutations having  $k$  occurrences of pattern  $p_0$  equals  $a_{n,k}^1 = c(n, k+1)$ .*

*Proof.* An  $n$ -length permutation  $\sigma \in A_{n,k}^0$  can be uniquely obtained from an  $(n-1)$ -length permutation  $\pi$  by one of the two following constructions:

- (i) if  $\pi \in A_{n-1,k-1}^0$ , then we increase by one all values of  $\pi$  and we add 1 at the end;
- (ii) if  $\pi \in A_{n-1,k}^0$ , then we increase by one all values of  $\pi$  greater than or equal to given value  $x$ ,  $1 < x \leq n$ , and we add  $x$  at the end.

We deduce the recurrence relation  $a_{n,k}^0 = a_{n-1,k-1}^0 + (n-1)a_{n-1,k}^0$  with the initial condition  $a_{n,0}^0 = (n-1)!$ , and then  $a_{n,k}^0 = a_{n,k}^1 = c(n, k+1)$ .  $\square$

Now, we focus on the distribution of the pattern  $p_2$ . Table 1 provides exact values for small sizes.

**Theorem 2.** *We have*

$$A^2(x, y) = \frac{e^{x(1-y)}}{(1-x)^y},$$

and the general term  $a_{n,k}^2$  satisfies for  $n \geq 2$  and  $1 \leq k \leq \lfloor \frac{n}{2} \rfloor$

$$a_{n,k}^2 = na_{n-1,k}^2 + (n-1)a_{n-2,k-1}^2 - (n-1)a_{n-2,k}^2$$

with the initial conditions  $a_{n,0}^2 = 1$  and  $a_{n,k}^2 = 0$  for  $n \geq 0$  and  $k > \lfloor \frac{n}{2} \rfloor$  (see Table 1 and the triangular table A136394 in [15]).

*Proof.* Let  $\sigma = \sigma_1\sigma_2 \dots \sigma_n$  denote a permutation of length  $n$  having  $k$  occurrences of pattern  $p_2$ . Let  $u_{n,k}$  (resp.  $v_{n,k}$ ) be the number of such permutations satisfying  $\sigma_n = n$  (resp.  $\sigma_n < n$ ). Obviously, we have

$$a_{n,k}^2 = u_{n,k} + v_{n,k}.$$

A permutation  $\sigma$  with  $\sigma_n = n$  can be uniquely constructed from an  $(n-1)$ -length permutation  $\pi$  as  $\sigma = \pi_1\pi_2 \dots \pi_{n-1}n$ . No new occurrences of  $p_2$  are created, and we obtain

$$u_{n,k} = a_{n-1,k}^2.$$

A permutation  $\sigma$  satisfying  $\sigma_n < n$  can be uniquely obtained from an  $(n-1)$ -length permutation  $\pi$  by adding a value  $x < n$  on the right side of its one-line notation, after increasing by one all the values greater than or equal to  $x$ . This construction creates a new pattern  $p_2$  if and only if  $\pi$  ends with  $n-1$ . Thus, we deduce

$$v_{n,k} = (n-1)u_{n-1,k-1} + (n-1)v_{n-1,k}.$$

Combining the equations, we obtain for  $n \geq 2$  and  $k \geq 1$

$$a_{n,k}^2 = na_{n-1,k}^2 + (n-1)a_{n-2,k-1}^2 - (n-1)a_{n-2,k}^2,$$

which implies the following differential equation

$$\frac{\partial A^2(x, y)}{\partial x} = (y-1)xA^2(x, y) + \frac{\partial (xA^2(x, y))}{\partial x}, \text{ where } A^2(x, 0) = 1.$$

A simple calculation provides the claimed closed form for the generating function  $A^2(x, y)$ .  $\square$

**Corollary 1.** For  $0 \leq i \leq 2$ , the patterns  $p_i$  are equipopular on  $S_n$ . Their popularity is given by the generalized Stirling number  $n! \cdot (H_n - 1)$  (see [A001705](#) in [15]) where  $H_n = \sum_{k=1}^n \frac{1}{k}$  is the  $n$ -th harmonic number.

*Proof.* The generating function of the popularity is directly deduced from the bivariate generating function of pattern distribution by calculating

$$\left. \frac{\partial A^1(x, y)}{\partial y} \right|_{y=1} = \left. \frac{\partial A^2(x, y)}{\partial y} \right|_{y=1}.$$

...								...
$\sum$	1	2	6	24	120	720	5040	40320

Table 1: Number of  $n$ -length permutations having  $k$  occurrences of  $p_2$  for  $0 \leq k \leq 4$  and  $1 \leq n \leq 8$ .

The statistic  $\mathbf{des}_2$  has a different distribution from  $\mathbf{des}_0$  and  $\mathbf{des}_1$ , but the three patterns  $p_0, p_1, p_2$  have the same popularity. Below we present a bijection on  $S_n$  that transports the statistic  $\mathbf{des}_2$  to the statistics  $\mathbf{pcyc} = \mathbf{cyc} - \mathbf{fix}$ .

**Theorem 3.** There is a one-to-one correspondence  $\phi$  on  $S_n$  such that for any  $\pi \in S_n$ , we have

$$\mathbf{des}_2 \pi = \mathbf{pcyc} \phi(\pi).$$

*Proof.* Let  $\pi$  be a permutation of length  $n$  having  $k$  occurrences of  $p_2$ . We decompose

$$\pi = B_0 \pi_{i_1} A_1 B_1 \pi_{i_2} A_2 B_2 \pi_{i_3} \dots \pi_{i_k} A_k B_k,$$

where

- $\pi_{i_1} < \pi_{i_2} < \dots < \pi_{i_k}$  are the tops of the occurrences of  $p_2$ , *i.e.* values  $\pi_{i_j} > \pi_{i_{j+1}}$  such that there does not exist  $\ell < i_j$  such that  $\pi_\ell > \pi_{i_j}$ ,
- $A_j$  is a maximal sequence such that all its values are lower than  $\pi_{i_j}$ ,
- for  $0 \leq j \leq k$ ,  $B_j$  is an increasing sequence such that  $\pi_{i_j} < \min B_j$  and  $\max B_j < \pi_{i_{j+1}}$ .

Now we construct an  $n$ -length permutation  $\phi(\pi)$  with  $k$  pure cycles as follows:

$$\phi(\pi) = \langle \pi_{i_1} A_1 \rangle \cdot \langle \pi_{i_2} A_2 \rangle \cdots \langle \pi_{i_k} A_k \rangle.$$

For instance, if  $\pi = 125346879$  then  $\phi(\pi) = \langle 5, 3, 4 \rangle \cdot \langle 8, 7 \rangle$ . The map  $\phi$  is clearly a bijection on  $S_n$  such that  $\mathbf{des}_2 \pi$  equals the number of pure cycles in  $\phi(\pi)$ .  $\square$

Note that  $\phi^{-1}$  is closely related to the Foata fundamental transformation.

### 3 The statistic $\mathbf{pex}$ of pure excedances

In order to prove the equidistribution of  $\mathbf{pex}$  and  $\mathbf{des}_2$ , regarding Theorem 3, it suffices to construct a bijection on  $S_n$  that transports pure excedances to pure cycles. Here, we first exhibit a bijection on the set  $D_n$  of  $n$ -length derangements (permutations without fixed points), then we extend it to the set of all permutations  $S_n$ .

Any permutation  $\pi \in S_n$  is uniquely decomposed as a product of transpositions of the following form:

$$\pi = \langle t_1, 1 \rangle \cdot \langle t_2, 2 \rangle \cdots \langle t_n, n \rangle$$

where  $t_i$  are integers such that  $1 \leq t_i \leq i$ . The transposition array of  $\pi$  is defined by  $T(\pi) = t_1 t_2 \dots t_n$ , which induces a bijection  $\pi \mapsto T(\pi)$  from  $S_n$  to the product set  $T_n = [1] \times [2] \times \dots \times [n]$ . By Lemma 1 from [1], the number of cycles of a permutation  $\pi$  is given by the number of fixed points in  $T(\pi)$ . Moreover, it is straightforward to check the two following properties:

- if  $t_i = i$ , then  $\pi_i = i$  if and only if there is no number  $j > i$  such that  $t_j = t_i = i$ ;
- if  $t_i = i$  and  $\pi_i \neq i$ , then  $i$  is the minimal element of a cycle of length at least two in  $\pi$ .

So, we deduce the following lemma.

**Lemma 1.** *The transposition array  $t_1 t_2 \dots t_n \in T_n$  corresponds to a derangement if and only if:  $t_i = i \Rightarrow$  there is  $j > i$  such that  $t_j = i$ .*

Given a derangement  $\pi = \pi_1\pi_2\dots\pi_n \in D_n$  and its graphical representation  $\{(i, \pi_i), i \in [n]\}$ . We say that the square  $(i, j) \in [n] \times [n]$  is *free* if all following conditions hold:

- (i) Neither  $\pi_i$  nor  $i$  is a position of a pure excedance;
- (ii)  $(i, j)$  is not on the first diagonal, *i.e.*  $j \neq i$ ;
- (iii) there does not exist  $k > i$  such that  $\pi_k = j$ ;
- (iv)  $j$  is not a pure excedance such that  $j < i$  and  $\pi^{-1}(j) < i$ ;
- (v) there does not exist  $k < i$ , with  $\pi_k = j > i$  such that all values of the interval  $[i, j - 1]$  appear on the right of  $\pi_i$  in  $\pi$ .

Whenever at least one of the statements above is not satisfied, we say that the square  $(i, j)$  is *unfree*. Notice that if  $i$  and  $\pi_i$  are not the positions of a pure excedance, then the square  $(i, \pi_i)$  is always free. So, for a column  $i$  of the graphical representation of  $\pi$  such that  $i$  and  $\pi_i$  are not the positions of a pure excedance, we label by  $j$  the  $j$ th free square from the bottom to the top. We refer to Figure 2 for an example of this labelling.

Now we define the map  $\lambda$  from  $D_n$  to the set  $T_n^\bullet$  of transposition arrays of length  $n$  satisfying the property of Lemma 1.

For a permutation  $\pi = \pi_1\pi_2\dots\pi_n \in D_n$ , we label its graphical representation as defined above, and  $\lambda(\pi) = \lambda_1\lambda_2\dots\lambda_n$  is obtained as follows:

- if  $i$  is a pure excedance in  $\pi$ , then we set  $\lambda_i = i$  and  $\lambda_{\pi^{-1}(i)} = i$ ;
- otherwise,  $\lambda_i$  is the sum of the label of the free square  $(i, \pi_i)$  with the number of pure excedances  $k < i$  such that  $\pi^{-1}(k) < i$ .

For instance, if  $\pi = 6\ 8\ 12\ 5\ 4\ 7\ 3\ 2\ 11\ 1\ 9\ 10$  then we obtain  $\lambda(\pi) = 1\ 1\ 2\ 4\ 4\ 2\ 1\ 1\ 9\ 1\ 9\ 10$  (see Figure 2).

Let us consider  $i$ ,  $1 \leq i \leq n$ . If  $i$  is a pure excedance of  $\pi$ , then we fix  $\lambda_i = i$  and  $\lambda_{\pi^{-1}(i)} = i < \pi^{-1}(i)$ . Otherwise, the square  $(i, i)$  is unfree, and all squares  $(i, \pi_k)$ ,  $i + 1 \leq k \leq n$ , are unfree, which implies that the number of free squares in the  $i$ th column is less than or equal to  $i$ . This means that  $\lambda(\pi)$  lies in  $T_n$ . Note that, by construction, all labeled squares do not correspond to any pure excedance. Now let us prove that the square  $(i, \pi_i)$  cannot be labeled  $i$ . Indeed, if  $\pi_i < i$  then the label of  $(i, \pi_i)$  is necessarily at most  $\pi_i \leq i - 1$ ; otherwise, if  $\pi_i > i$  then the fact that  $i$  is not a pure excedance implies that there is  $\pi_j \in [i, \pi_i - 1]$  with  $j < i$ . Let us choose the lowest  $j$  with this property. Using (v), the square  $(i, j)$  is unfree, which implies that

the label of  $(i, \pi_i)$  is less than or equal to  $n$  minus the minimal number of unfree squares  $(i, j)$  in column  $i$ , that is  $n - (n - i + 1) = i - 1$ . Moreover, the transposition array  $\lambda(\pi)$  has exactly  $\mathbf{pex} \pi$  fixed points, and for any fixed point  $i$  there necessarily exists  $j = \pi^{-1}(i) > i$  such that  $\lambda_j = \lambda_i = i$ . This implies that  $\lambda(\pi) \in T_n^\bullet$ .

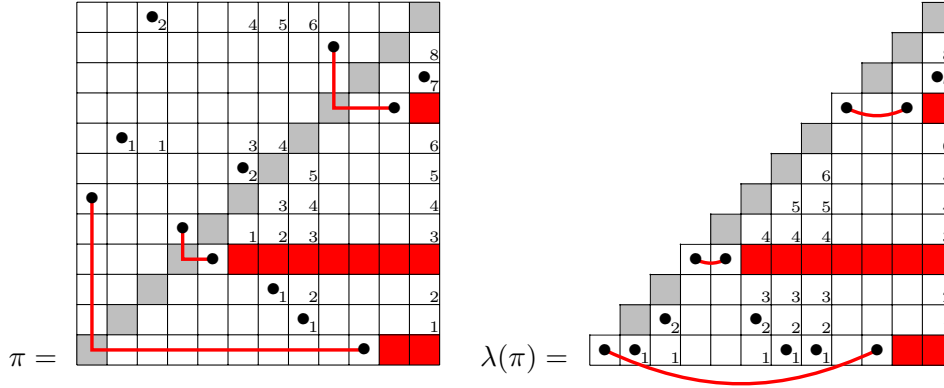

Figure 2: Illustration of the bijection  $\lambda$  for  $\pi = 6\ 8\ 12\ 5\ 4\ 7\ 3\ 2\ 11\ 1\ 9\ 10$  and  $\lambda(\pi) = 1\ 1\ 2\ 4\ 4\ 2\ 1\ 1\ 9\ 1\ 9\ 10$ .

**Theorem 4.** *The map  $\lambda$  from  $D_n$  to  $T_n^\bullet$  is a bijection such that*

$$\mathbf{pex} \pi = \mathbf{fix} \lambda(\pi).$$

*Proof.* Since the cardinality of  $T_n^\bullet$  equals that of  $D_n$ , and the image of  $D_n$  by  $\lambda$  is contained in  $T_n^\bullet$ , it suffices to prove the injectivity.

Let  $\pi$  and  $\sigma$ ,  $\pi \neq \sigma$ , two derangements in  $D_n$ . If  $\pi$  and  $\sigma$  do not have the same pure excedances, then, by construction,  $\lambda(\pi)$  and  $\lambda(\sigma)$  do not have the same fixed points, and thus  $\lambda(\pi) \neq \lambda(\sigma)$ .

Now, let us assume that  $\pi$  and  $\sigma$  have the same pure excedances. If there is a pure excedance  $i$  such that  $\pi^{-1}(i) \neq \sigma^{-1}(i)$  then the definition implies  $\lambda(\pi) \neq \lambda(\sigma)$ . Otherwise the two permutations have the same pure excedances  $i$ , and for each of them we have  $\pi^{-1}(i) = \sigma^{-1}(i)$ . Let  $j$  be the greatest integer such that  $\pi_j \neq \sigma_j$  (without loss of generality, we assume  $\pi_j < \sigma_j$ ). In this case,  $j$  is not a pure excedance for the two permutations. Thus,  $\lambda(\pi)_j$  (resp.  $\lambda(\sigma)_j$ ) is the sum of the label of  $(j, \pi_j)$  (resp.  $(j, \sigma_j)$ ) with the number of pure excedances  $k < j$  such that  $\pi^{-1}(k) < j$  (resp.  $\sigma^{-1}(k) < j$ ). Since we

have  $\pi_j < \sigma_j$ , the label of  $(j, \pi_j)$  is less than the label of  $(j, \sigma_j)$ , and the number of pure excedances  $k < j$  such that  $\pi^{-1}(k) < j$  is less than or equal to the number of pure excedances  $k < j$  such that  $\sigma^{-1}(k) < j$ . Then we have  $\lambda(\pi)_j < \lambda(\sigma)_j$ . Then  $\lambda$  is an injective map, and thus a bijection.  $\square$

**Theorem 5.** *There is a one-to-one correspondence  $\psi$  on the set  $D_n$  of  $n$ -length derangements such that for any  $\pi \in D_n$ ,*

$$\mathbf{pex} \pi = \mathbf{cyc} \psi(\pi).$$

*Proof.* Considering Theorem 3 and Theorem 4, we define for any  $\pi \in D_n$ ,  $\psi(\pi) = \phi(\sigma)$  where  $\sigma$  is the permutation having  $\lambda(\pi)$  as transposition array.  $\square$

**Theorem 6.** *The two bistatistics  $(\mathbf{pex}, \mathbf{fix})$  and  $(\mathbf{pcyc}, \mathbf{fix})$  are equidistributed on  $S_n$ .*

*Proof.* Considering Theorem 5, we define the map  $\bar{\psi}$  on  $S_n$ . Let  $\pi'$  be the permutation obtained from  $\pi$  by deleting all fixed points and after normalization as a permutation. Let  $I = \{i_1, i_2, \dots, i_k\}$  be the set of fixed points of  $\pi$ . Then, we set  $\pi'' = \psi(\pi')$ . So,  $\sigma = \bar{\psi}(\pi)$  is obtained from  $\pi''$  by inserting fixed points  $i \in I$  after a shift of all other entries in order to produce a permutation in  $S_n$ . By construction, we have  $\mathbf{pex} \pi = \mathbf{pcyc} \sigma$  and  $\mathbf{fix} \pi = \mathbf{fix} \sigma$  which completes the proof.  $\square$

A byproduct of this theorem is

**Corollary 2.** *The statistics  $\mathbf{cyc}$  and  $\mathbf{pex} + \mathbf{fix}$  are equidistributed on  $S_n$ .*

Also, a direct consequence of Theorem 3 and Theorem 6 is

**Theorem 7.** *The two statistics  $\mathbf{pex}$  and  $\mathbf{des}_2$  are equidistributed on  $S_n$ .*

Notice that the Foata's first transformation is not a candidate for proving the equidistribution of  $\mathbf{pex}$  and  $\mathbf{des}_2$ , while it transports  $\mathbf{exc}$  to  $\mathbf{des}$ .

**Corollary 3.** *For  $0 \leq i \leq 2$ , the patterns  $p_i$  and  $pex$  are equipopular on  $S_n$  (see [A001705](#) in [15]).*

Finally, we present two conjectures for future works.

**Conjecture 1.** *The two bistatistics  $(\mathbf{des}_2, \mathbf{cyc})$  and  $(\mathbf{pex}, \mathbf{cyc})$  are equidistributed on  $S_n$ .*

**Conjecture 2.** *The two bistatistics  $(\mathbf{des}_2, \mathbf{des})$  and  $(\mathbf{pex}, \mathbf{exc})$  are equidistributed on  $S_n$ .*

It is interesting to remark that  $(\mathbf{des}, \mathbf{cyc})$  and  $(\mathbf{exc}, \mathbf{cyc})$  are not equidistributed. Indeed, there are 3 permutations in  $S_3$  having  $\mathbf{exc} = 1$  and  $\mathbf{cyc} = 2$ , namely 132, 213, 321, but only 2 permutations with  $\mathbf{des} = 1$  and  $\mathbf{cyc} = 2$ , videlicet 132 and 213. So, if the conjectures 1 and 2 are true then their proofs are probably independent.

## Acknowledgements

We would like to greatly thank Vincent Vajnovszki for having offered us Conjecture 2.
